# EXPERIMENT NO : 10

Aim:
To learn Dockerfile instructions, build an image for sample web application using DOCKERFILE

Theory :

Docker is a platform designed to make it easier to create, deploy, and run applications by using containers. Containers allow a developer to package up an application with all parts it needs, such as libraries and other dependencies, and ship it all out as one package. Here's a detailed look at the basics of Docker:

**1.** What is Docker?

Docker is an open-source platform that automates the deployment of applications inside lightweight, portable containers. A container is a standard unit of software that packages up code and all its dependencies so the application runs quickly and reliably from one computing environment to another.

---

**2.** Key Concepts in Docker

Containers

- Definition: Containers are isolated environments where applications run with everything they need to function.

- Features: They are lightweight, fast, and share the host OS kernel, making them more efficient than virtual machines.

Images

- Definition: An image is a read-only template used to create containers. It includes the application code, libraries, and other dependencies.

1

- How it works: You build an image, then run a container based on that image.

Docker Engine

- The core component of Docker that runs and manages containers.

- It has two main parts:

  - Server: A long-running daemon process (dockerd) that manages containers.

  - Client: The command-line interface (docker) that users interact with.

Docker Hub & Registry

- Docker Hub: A cloud-based registry service where Docker images are stored and shared.

- Registry: A service for storing and distributing Docker images. Docker Hub is the default registry, but you can set up private registries.

---

**3.** How Docker Works

- Dockerfile: A script that contains instructions to assemble a Docker image. It defines the base image, application code, and dependencies.

- Building Images: Using the command docker build, Docker reads the Dockerfile and creates an image.

- Running Containers: Using docker run, Docker starts a container from an image.

---

**4.** Why Use Docker?

- Portability: Containers can run on any system that has Docker installed, regardless of the underlying hardware or OS.

- Consistency: The application runs the same way in development, testing, and production environments.

Vedanshi Shethia
2311137

- Isolation: Each container is isolated from others, preventing conflicts between applications.

- Efficiency: Containers are lightweight, using fewer resources compared to virtual machines.

---

**5.** Basic Docker Commands

- docker --version: Check Docker version.

- docker pull <image>: Download an image from Docker Hub.

- docker build -t <name> .: Build an image from a Dockerfile.

- docker run <image>: Run a container from an image.

- docker ps: List running containers.

- docker ps -a: List all containers (including stopped ones).

- docker stop <container_id>: Stop a running container.

- docker rm <container_id>: Remove a container.

- docker rmi <image_name>: Remove an image.

---

**6.** Docker Compose

- A tool for defining and running multi-container Docker applications.

- Uses a YAML file (docker-compose.yml) to configure services, networks, and volumes.

- Command: docker-compose up to start all services defined in the file.

---

**7.** Real-World Use Cases

Vedanshi Shethia
2311137

Vedanshi Shethia
2311137

- Microservices Architecture: Running different microservices in isolated containers.

- Continuous Integration/Continuous Deployment (CI/CD): Automating testing and deployment processes.

- DevOps and Infrastructure as Code: Simplifying the deployment of complex applications.

Output:

Conclusion :

Docker revolutionizes the software development and deployment process by providing a powerful platform for
containerization. By encapsulating applications and their dependencies into lightweight, portable containers.
